

ES 215: Assignment 2

Roll No: 20110132

Name: Prey Patel

[Github Link](#)

Q1. MIPS32 assembly that computes the Highest value & index, Lowest value & index and Average value of an Array A[0..20].

Github file Q1.s

Took an array of size 20.

The screenshot displays a MIPS32 assembly simulator interface. On the left, the 'FP Regs' and 'Int Regs [16]' tabs are visible. The 'Int Regs [16]' tab shows the following register values:

Register	Value
HI	0
LO	a
R0 [x0]	0
R1 [at]	10010000
R2 [v0]	a
R3 [v1]	0
R4 [a0]	a
R5 [a1]	7ffff1ec
R6 [a2]	7ffff1f4
R7 [a3]	0
R8 [t0]	10010050
R9 [t1]	14
R10 [t2]	14
R11 [t3]	13
R12 [t4]	f
R13 [t5]	1
R14 [t6]	0
R15 [t7]	a
R16 [s0]	0
R17 [s1]	0
R18 [s2]	0
R19 [s3]	0
R20 [s4]	0
R21 [s5]	0
R22 [s6]	0
R23 [s7]	0
R24 [t8]	a
R25 [t9]	0
R26 [k0]	0
R27 [k1]	0
R28 [gp]	10008000
R29 [sp]	7ffff1e8
R30 [s8]	0
R31 [ra]	400018

The 'Data' tab shows the 'User data segment [10000000]..[10040000]' with the following values:

Address	Value
[10000000]	00000000
[10010000]	00000001
[10010010]	00000002
[10010020]	00000003
[10010030]	00000004
[10010040]	00000005
[10010050]	00000006

Q2. Consider a dual core processor. Program A completes in 6 seconds on core 1 and has a CPI of 6 and program B completes in 5 seconds on core 2 and has a CPI of 5. Both cores run at 1 GHz. What is the combined throughput of the processor?

Program A has CPI of 6 and takes 6 seconds on a 1 GHz processor on core 1.

For core 1 with program A :

Suppose program A has x instructions then,

6x cycles as CPI is 6.

6 seconds with 1GHz processors.

$$6 * x = 6 * 10^9$$

$$x = 10^9 \text{ instructions}$$

So program A has 10^9 instructions.

$$\text{Throughput, } T_1 = \frac{10^9 \text{ instructions}}{6 \text{ seconds}} = 1/6 * 10^9 \text{ Instructions per second}$$

Similarly, For core 2 with program B :

Suppose program B has x instructions then,

5x cycles as CPI is 5.

5 seconds with 1GHz processors.

$$5 * x = 5 * 10^9$$

$$x = 10^9 \text{ instructions}$$

So program B has 10^9 instructions.

$$\text{Throughput, } T_2 = \frac{10^9 \text{ instructions}}{5 \text{ seconds}} = 1/5 * 10^9 \text{ Instructions per second}$$

Total throughput of processor = Throughput of core 1 + Throughput of core 2

$$= (1/6 + 1/5) * 10^9 \text{ IPS}$$

$$= 11/30 * 10^9 \text{ IPS} = 3.67 * 10^9 \text{ IPS}$$

Q3. Say a processor X runs at 2 GHz and a program (Program A) executes 10 billion instructions with avg. CPI of 3. Compute how long this program ran for? Now, suppose we got another processor Y with a clock frequency of 4 GHz. Program A on this new processor executes 7 billion instructions with an average CPI of 5. What is the speedup (if any) of program A on processor Y over processor X?

For processor X -> 2 GHz -> 2 billion cycles per second

Program A with processor X:

Number of instructions = 10 billion

avg. CPI = 3

total number of cycles required = 30 billion cycles

$$\text{Time with processor X} = \frac{30 \text{ billion cycles}}{2 \text{ billion cycles per second}} = 15 \text{ seconds}$$

So program A will require 15 seconds with processor X.

Now, for processor Y -> 4 GHz -> 4 billion cycles per second

Program A with processor Y:

Number of instructions = 7 billion

avg. CPI = 5

total number of cycles required = 35 billion cycles

$$\text{Time with processor Y} = \frac{35 \text{ billion cycles}}{4 \text{ billion cycles per second}} = 8.75 \text{ seconds}$$

So program A will require 8.75 seconds with processor Y.

$$\text{Speedup} = \frac{\text{execution time on X}}{\text{execution time on Y}} = 15/8.75 = 1.714$$

Q4. Consider a Processor with 1 GHz. Program A executes 9 billion instructions on this processor and has an average CPI of 1.5. With a newly designed processor that can run at 2 GHz, the execution time of Program A dropped to a quarter of the original value. What is the average CPI of Program A on the new design?

$$\text{Execution time} = \frac{\text{Num of instructions} * \text{CPI}}{\text{Cycle frequency of processor}}$$

$$\text{exeTime}_1 = 4 * \text{exeTime}_2$$

$$\frac{9 * 10^9 * 1.5}{10^9} = 4 * \frac{9 * 10^9 * x}{2 * 10^9}$$

$$x = 0.75$$

Average CPI of program A on new design is 0.75.

Q5. Suppose a processor consumes 80 watts of power (Note: it is the total power) while running at 2 GHz and the operating voltage of this processor is 5V.

Total power = 80 W

Clock frequency = 2GHz

Operating voltage = 5V

Assuming static power is 25 % of the total power.

Then dynamic power = 60 W and Static power = 20 W

- a) How much dynamic power would the same processor consume if the frequency were to be frequency to 5 GHz?

Dynamic power is proportional to frequency,
So for 5 GHz frequency,

$$\text{Dynamic power} = \frac{5 * 10^9}{2 * 10^9} * 60 = 150 \text{ W}$$

- b) With technology scaling, consider that operating voltage drops to 2V. Now for the 2GHz processor, what is the overall power consumption with this design and what fraction of the power can be attributed to static power?

static power is proportional to the voltage.

$$\text{New static power} = \frac{2}{5} * 20 = 8 \text{ W}$$

Also dynamic power is proportional to square of voltage.

$$\text{New dynamic power} = \left(\frac{2}{5}\right)^2 * 60 = 9.6 \text{ W}$$

$$\text{So new total power} = 9.6 + 8 = 17.6 \text{ W}$$

$$\text{Fraction of static power} = 8/17.6 = 0.455$$

Grace Question:

Part a)

Files are uploaded on the github.

Part b)

Preprocessed files for MIPS architecture are generally expected to be larger than those for x86 architecture. This is because the MIPS architecture may require more intermediate code or expanded macros during preprocessing compared to x86. Compiled files for MIPS architecture may tend to be larger or similar in size compared to those for x86 architecture. This could be due to variations in the generated assembly code, optimizations, or instructions used by the compiler for each architecture. Assembled files for MIPS architecture may be expected to be smaller or similar in size compared to those for x86 architecture. This difference could stem from differences in instruction sets, encoding, or optimizations performed during the assembly process. Binary executable files for MIPS architecture are generally expected to be smaller or similar in size compared to those for x86 architecture. This difference could be influenced by various factors such as compiler optimizations, runtime libraries, and differences in executable formats.
